

## 2.5 Acid–Base Titrations

### *Problems Worksheet*

1. A primary standard is the starting point for a titration.
  - a. Explain the role of a primary standard in volumetric analysis.
  - b. Why is NaOH not suitable for use as a primary standard?
  - c. Explain why a high molar mass is preferable for a primary standard.
  - d. Why should a primary standard be stored in a desiccator before it is weighed?
  - e. Explain what is meant by a secondary standard and give an example of how it is produced.

2. Determine the mass of solid required to make the following primary standard solutions:
- 0.100 mol.L<sup>-1</sup> oxalic acid in a 500 mL volumetric flask. Oxalic acid available for use as a primary standards is a dihydrate with the formula H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·2H<sub>2</sub>O.
  - 0.0500 mol.L<sup>-1</sup> sodium carbonate (Na<sub>2</sub>CO<sub>3</sub>) in a 250 mL volumetric flask.
3. Explain the purpose of the following equipment used in titrations:
- Volumetric flask
  - Pipette
  - Burette

4. Mason is going to determine the concentration of an approximately  $0.1 \text{ mol.L}^{-1}$  HCl solution by titrating it against his primary standard solution of  $\text{Na}_2\text{CO}_3$ . He is putting the HCl in the burette and the  $\text{Na}_2\text{CO}_3$  in the conical flask.
- When making the primary standard, Mason struggles to weigh out the exact mass he needs. The mass of  $\text{Na}_2\text{CO}_3$  he adds to his 250 mL volumetric flask is 2.625 g. What is the concentration of his primary standard?
  - What should he use to rinse the pipette and the burette?
  - If he rinses the conical flask with the  $\text{Na}_2\text{CO}_3$  solution, how will this affect the titration?
  - If he decided to put the acid in the conical flask and the base in the burette, how would this affect the results on the titration?

5. When performing a titration, a reading needs to be taken from the burette at the start and at the end.
- Why is the burette read from the bottom of the meniscus?

- What is the reading on this burette?
- What is the uncertainty on this burette reading?

6. Explain the difference between the end point and the equivalence point in a titration.

7. For each of the following titrations, state the approximate pH at the equivalence point and state which indicator(s) would be most suitable.

|                  | 2         | 3          | 4         | 5             | 6               | 7         | 8          | 9      | 10     |
|------------------|-----------|------------|-----------|---------------|-----------------|-----------|------------|--------|--------|
| methyl orange    | red       | orange-red | orange    | yellow-orange | yellow          | yellow    | yellow     | yellow | yellow |
| bromothymol blue | yellow    | yellow     | yellow    | yellow        | greenish-yellow | green     | blue-green | blue   | blue   |
| phenolphthalein  | colorless | colorless  | colorless | colorless     | colorless       | colorless | pink       | pink   | pink   |

- HCl and  $\text{Na}_2\text{CO}_3$
- KOH and HCl
- NaOH and  $\text{CH}_3\text{COOH}$
- $\text{H}_2\text{C}_2\text{O}_4$  and NaOH

8. Performing a titration between a weak acid (such as  $\text{CH}_3\text{COOH}$ ) and a weak base (such as  $\text{NH}_3$ ) is difficult.
- Why is this more challenging than a titration where a strong acid or base is involved?

- How can this titration be performed if it is necessary?

9. Sketch a titration curve for the following titrations. Assume that the equivalence point occurs at 20 mL :
- KOH and HCl with the acid in the burette.

b. NaOH and CH<sub>3</sub>COOH with the base in the burette.

c. H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> and NaOH with the acid in the burette.
