

Naming Rules

1. Identify the longest carbon chain. This chain is called the parent chain and is named based on this number (methane, ethane, propane, etc.).
2. Identify all of the substituents (groups appending from the parent chain). These may include methyl, ethyl, propyl, iodo, chloro, bromo, nitro, fluoro.
3. Number the carbons of the parent chain from the end that gives the substituents the lowest numbers. If two or more side chains are in equivalent positions, assign the lowest number to the one which will come first in the name.
4. If the same substituent occurs more than once, the location of each point on which the substituent occurs is given. In addition, the number of times the substituent group occurs is indicated by a prefix (di, tri, tetra, etc.).
5. If there are two or more different substituents they are listed in alphabetical order using the base name (ignore the prefixes).
6. A cyclic hydrocarbon is designated by the prefix cyclo- which appears directly in front of the base name.
7. Commas are used between numbers and dashes are used between letters and numbers. There are no spaces in the name.

eg.

8. Double bonds in hydrocarbons are indicated by replacing the suffix -ane with -ene. If there is more than one double bond, the suffix is expanded to include a prefix that indicates the number of double bonds present (-adiene, -atriene, etc.). Triple bonds are named in a similar way using the suffix -yne. The position of the multiple bond(s) within the parent chain is(are) indicated by placing the number(s) of the first carbon of the multiple bond(s) directly in front of the base name.
9. When numbering the carbons of the parent chain multiple bonds always have the lowest possible numbers.

eg.
