

INCOMPLETE DOMINANCE (BLENDING)

This occurs when a particular characteristic is neither completely dominant nor recessive.

This results in the offspring showing a "blending" of the characteristics, giving an "in-between" or "blended" characteristic.

This means that the offspring looks different to the parents.

Examples

- Japanese snapdragon flowers have red (RR) and white (WW) are the two colours shown by pure-breeding plants. Red incompletely dominates white flower colour.

If the flowers are crossed, the resulting seeds produce pink (RW) flowers. ***What is seen is a totally new colour - the red and white are not visible.***

Note that the alleles are represented by TWO CAPITAL LETTERS - not one letter of the alphabet with upper and lower case.

Consider the crossing of a pink snapdragon flower with a white flower.

- In budgerigars, blue colour (BB) incompletely dominates yellow colour (YY). The hybrid characteristic is a green colour (BY).

Consider the crossing of two hybrid green budgies.

CO-DOMINANCE

Co-dominant characteristics **both show** at the same time. **Both characteristics can be seen** - there is **NO** "blending" or "in-between" characteristic.

Examples

- In poll shorthorn cattle, red coat colour (RR) co-dominates with white coat colour (WW).

In a heterozygous (hybrid) individual, both the red and white hairs show in the coat when observed close up. From a distance, the hair colours seem to "merge" into a roan colour effect - the eyes can't distinguish the red and white hair.

Consider the crossing of a red bull with a roan cow.

- Human blood types show co-dominance. A and B co-dominate while o is recessive.

Blood Type	Genes
A	AA or Ao
B	BB or Bo
AB	AB
O	oo

Consider the possible blood types of children born to a male with Ao blood and a woman who has Bo blood.
