

EXCRETION

Excretion: the removal of waste products from respiration within cells.

The circulatory system (specifically the blood) carries the waste products from respiration in the cells to the organs responsible for excretion - the ***lungs, skin*** and ***kidneys***.

If the waste products are not removed from the body, they would poison the body and end in death.

The waste products are ***CO₂, H₂O*** and ***urea***.

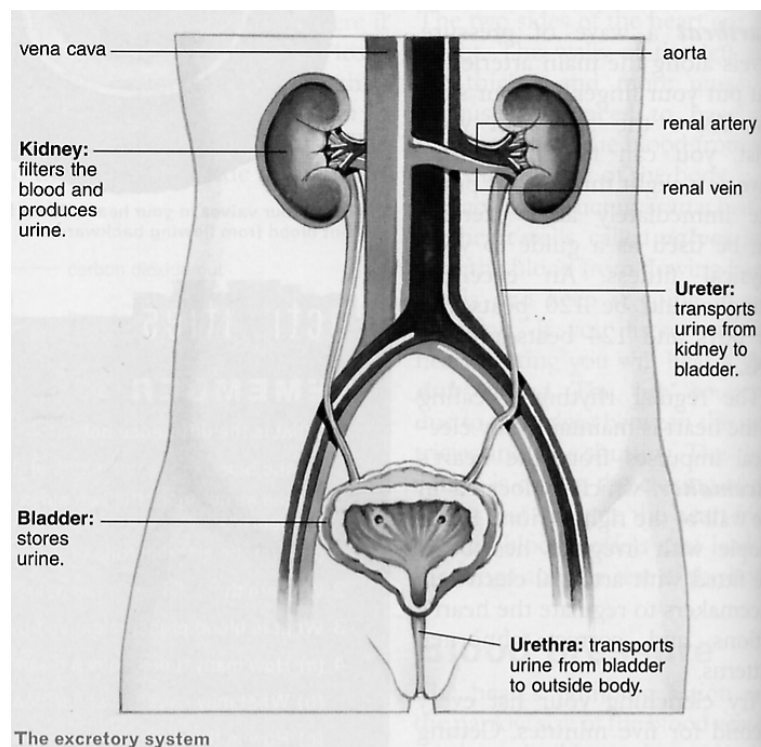

The ***solid material passed out of the anus is not a waste product from respiration*** - it is undigested food and fibre called ***faeces***.

This process is called ***elimination*** or ***defaecation***.

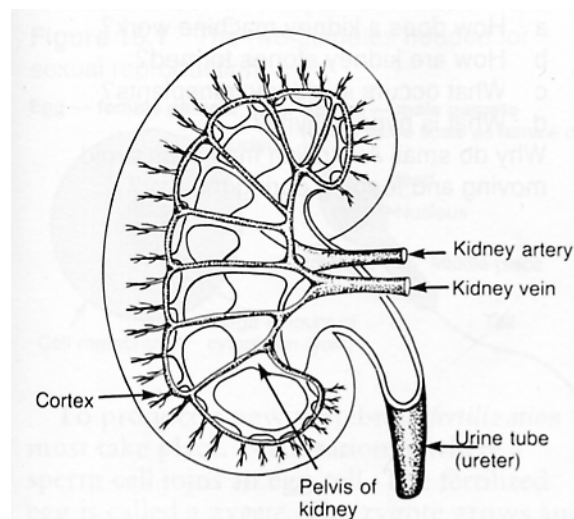

Urea is a toxic waste filtered from the blood by the kidneys. It is collected in the bladder and formed into ***urine*** (by adding H₂O) and then passed out of the body.

ORGAN	EXCRETORY PRODUCT
lungs	CO ₂ , H ₂ O
skin	H ₂ O
kidneys	H ₂ O, urea

Structure of the System

Structure of the Kidney

Cortex - filters the blood and collects the urea and water.

Pelvis - area where the urea and water collects to form urine.

Ureter - fine tubes that conduct the urine down to the bladder.
